VOLUME 1 | NO. 2 | 2013

mefanet JOURNAL

An overview of currently available methods and future trends for physical activity

Education of data mining as novel approach in clinical and health care research

LMS Moodle in teaching biophysics and medical informatics at Faculty of Medicine, University of Ostrava

Japan Society for Medical Education (JSME): its history and activities for the last 45 years

The use of mobile devices in medical education

AKOFTM-C2 algorithm and SEPSIS-Q scenario as interactive tools for problem based learning sessions in medical education

Scope of the journal

Manuscripts are invited which deal with the following topics:

- E-health and telemedicine
- E-learning
- Information science
- Innovative teaching methods
- Medical educational informatics and learning analytics
- Modelling and simulation
- Multimedia
- Social media pedagogy
- Evidence-based medicine in education

Peer Review Process

Each article corresponding to journal's focus will undergo a review process. The review process is double-blinded; the author does not know the reviewers and vice versa. Each article is reviewed by at least by two reviewers nominated by the editorial board.

The Mefanet J accepts following types of articles:

- Reviewed: original article, review
- Not reviewed: comment, editorial, tutorial

becoming acutely unwell [6]. This type of education has lots of benefits in professional training of nurses. It is realized in safe, controlled and realistic environment of simulation laboratories reflecting real hospital and community care environment (specific clinical environment) with no risk of harming real patients. Simulation can be also used to train individuals in the context of team activities, creating a more realistic clinical environment. It contributes to creation of learning environment that is supportive, challenging, constructive, motivated, engaging, skilled, flexible, inspiring and respectful [14]. Thus simulation education is effective, interactive, interesting, efficient and modern way of nursing education. The use of simulation as a teaching strategy can contribute to patients' safety and optimize outcomes of care, providing learners with opportunities to experience scenarios and intervene in clinical situations within a safe, supervised setting without posing a risk to a patient [4]. This is excellent teaching strategy for many

skills, particularly in critical care nursing. It can be used in professional training of nurses to teach theory, assessment, technology, pharmacology, clinical knowledge and critical thinking [4].

The EU RADAR IP programme brought benefits to both the students and the teachers. It allowed the students to gain new knowledge and practical skills and competences in a pan-European academic setting (multicultural), and to make new friends. For teachers it was a great opportunity to acquire new methods, mutual inspiration and motivation to introduce and implement progressive teaching methods. In order to improve professional training of nurses, further details of the project are presented on the EU RADAR project webpage (<http://www.radar.org>), and part of the project will continue at the Pula University of Applied Sciences in Germany, in February 2014.

ABSTRACT — This paper describes the interactive tools of the AKUTNE.CZ (part of MEFANET) and SEPSIS-Q portals for Problem Based Learning (PBL) sessions in medical education. The portals aim to be a comprehensive source of information and educational materials, covering all aspects of acute medicine for undergraduate medical students and health professionals. Our focus is mainly on simulation-based tools for teaching and learning a workflow in acute patient care, the toolbox of the AKUTNE.CZ and SEPSIS-Q portals. Over the last five years, the toolbox of the AKUTNE.CZ and SEPSIS-Q portals has been developed and published online, allowing users to test www.litru.eu have been developed and published online, allowing users to test and improve their knowledge and skills in the field of acute medicine. Additionally, we have created six SEPSIS-Q interactive scenarios in General Medicine (First Aid, Anesthesiology and Pain Management, Emergency Medicine) and in Nursing (Obstetric Analgesia and Anesthesia for Midwives, Intensive Care and in Nursing (Obstetric Analgesia and Anesthesia for Midwives, Intensive Care and in Nursing). The interactive scenarios serve to demonstrate interesting cases, with preference for Intensive Care Medicine sessions in General Medicine and Nursing.

INTRODUCTION

Acute/intensive care/critical care/emergency medicine is a dynamic and time-pressure environment with high demands on crisp team communication and leadership, accurate clinical reasoning and often, immediate decision-making. Simulating such an environment offers good techniques for training multidisciplinary medical teams, facilitating drilled interaction and coordination, and enabling the team to function as an effective unit [1]. The Internet education resources for critical care medicine have been recently reviewed by Klempell et al. [2]. The authors deduce that the majority of these resources are only electronic forms of textbooks and articles rather than interactive algorithms and dynamic simulations. Davids et al. [3] described an interactive web-based simulation in which the user treats patients with electrolyte and acid-base disorders, selects therapies

and dosage, and obtains immediate feedback on the treatment results. The GOLEM system devised at the Charles University in Prague (Kofránek et al.) simulates many different clinical situations (e.g., circulatory insufficiency, renal disorders, diarrhoea, etc.) where the user has the option of working on the cases in virtual worlds, as in the case of Second Life [5].

Apart from the cited studies, medical education in general is undergoing significant shift from traditional methods (textbooks, lectures, bedside teaching) to a more comprehensive approach, which includes modern ICT tools (e-learning, interactive algorithms, computer simulations, virtual patients). The new approach has been shown to improve the learning skills of medical students and residents

ABSTRACT — This paper describes the interactive tools of the AKUTNE.CZ (part of MEFANET) and SEPSIS-Q portals for Problem Based Learning (PBL) sessions in medical education. The portals aim to be a comprehensive source of information and educational materials, covering all aspects of acute medicine for undergraduate medical students and health professionals. Our focus is mainly on simulation-based tools for teaching and learning a wide range of acute patient care, the toolbox of the AKUTNE.CZ and SEPSIS-Q portals. Over the last five years, more than 30 interactive algorithms in the Czech and English languages (<http://www.litza.eu>) have been developed and published online, allowing users to test and improve their knowledge and skills in the field of acute medicine. Additionally, we have created six SEPSIS-Q interactive scenarios in General Medicine (Intensive Care and Internal Medicine), Anesthesiology and Pain Management, Emergency Medicine and in Nursing (Obstetric Anesthesia and Anesthesia for Midwives, Intensive Care and in Nursing). The interactive scenarios serve to demonstrate interesting cases, with preference for Intensive Care Medicine sessions in General Medicine and Nursing.

INTRODUCTION

Acute/intensive care/critical care/emergency medicine is a dynamic and time-pressure environment with high demands on crisp team communication and leadership, accurate clinical reasoning and often, immediate decision-making. Simulating such an environment offers good techniques for training multidisciplinary medical teams, facilitating drilled interaction and coordination, and enabling the team to function as an effective unit [1]. The Internet education resources for critical care medicine have been recently reviewed by Klempell et al. [2]. The authors deduce that the majority of these resources are only electronic forms of textbooks and articles rather than interactive algorithms and dynamic simulations. Davids et al. [3] described an interactive web-based simulation in which the user treats patients with electrolyte and acid-base disorders, selects therapies

and dosage, and obtains immediate feedback on the treatment results. The COLEM system devised at the Charles University in Prague (Kofránek et al.) simulates many different clinical situations (e.g., circulatory insufficiency, renal disorders, diarrhoea, etc.) where the user has the option of working on the cases jointly with fellow students via the Internet.

Apart from the cited studies, medical education in general is undergoing significant shift from traditional methods (textbooks, lectures, bedside teaching) to a more comprehensive approach, which includes modern ICT tools (e-learning, interactive algorithms, computer simulations, virtual patients). The new approach has been shown to improve the learning skills of medical students and residents.

EDUCATION OF DATA MINING AS A NOVEL APPROACH IN CLINICAL AND HEALTH CARE PRACTICE

ABSTRACT— Data mining (DM) is a widely adopted methodology for the analysis of large datasets which is on the other hand often overestimated as merely considered as a universal solution. This statement is obvious for clinical practice in which large and heterogeneous datasets are often present. DM is a specific standard methods available in common statistical software and can be divided into a complex workflow methodology covering all the steps of obtaining the data acquisition through pre-processing and data analysis to interpretation of the results. The whole workflow is aimed at one final goal – to find any interesting, non-trivially hidden and potentially useful information. This innovative concept of data mining was adopted in our educational course of the Faculty of Medicine at the Masaryk University accessible from its e-learning platform www.med.muni.cz/lanek-318-zavedeni-technologie-data-mining-a-ovplyvni-genytech-expressnich-map-do-vysky.html.

INTRODUCTION

The term "data mining" (DM) is currently widespread in all areas related to data analysis. Clinical research belongs to them as well and the application of complex computational methods has become very popular in this area because of increasing amount of available data. The DM concept is nevertheless often overestimated or incorrectly considered as a universal solution for all problems. Although data mining seems to be well defined, the opposite is true. Even its definition is problematic and there are many definitions books and web portals dealing with the data mining. There are two probably the most popular definitions: "The nontrivial extraction of implicit, previously unknown, and potentially useful information from data" [1] and "The science of extracting useful information from large data sets or databases" [2].

In the article we would like to introduce our educational materials presenting concepts and approaches of data mining for clinicians and other researchers in clinical and health care fields.

DM is mostly considered in the relation to large datasets; its usage in the commercial applications is

common as well. In fact, the DM is a well established methodology applicable to any data analysis and it is not "owned" by any area of science. The DM has been adopted in wide area of applications, such as marketing of risk clients, non-legal usage of email messages, e-mail classification and spam message detection, text and speech recognition or molecular data analysis. Therefore, the DM is the area of science which development is multidisciplinary in its nature. Methods applicable in commercial applications are being applied in any other research areas and vice versa.

Data mining is often connected to an idea of general machine learning previously unknown information from the data and the methodology is often presented as a "black box" with simplified description. The reality is of course more rational. Good knowledge of mathematical background of the DM methods and their limitations is crucial for the correct application of the DM; the most important is expert knowledge and long-term experience. Methods applied in DM are principally multivariate and have to follow all rules of multivariate data analysis. The benefits of multivariate methods are as follows [3]:

- Visualization of data with multiple variables
- Searching of meaningful views on multivariate data, identification of importance and hierarchy of variables
- Identification of correlations among variables, simplification of their structure
- Analysis of similarities between analysed subjects, their stratification, classification and prediction

The question is whether the data mining is in any way different from the commonly adopted statistical methods? The answer is both yes and no. DM uses methods available in common statistical packages and "mining" can be sometimes used as a marketing term only. On the other hand, even common statistical methods are used in novel, complex and logically joined context. The real DM is a standardized complex methodology covering all the steps of data analysis from data acquisition through pre-processing and data analysis to interpretation of the results; the example is CRISP-DM, JDM (Java Data Mining) or complex methods of formal description such as PMML (Predictive Model Markup Language). The data mining thus brings new quality in data analysis which is more related to innovative combination of methods than to any single method. DM in the hands of experienced data analyst is an important tool of scientific data analysis to be applied on complex heterogeneous multivariate data.

The workflow of data mining can be separated into simple individual steps from data storage and pre-processing to their description and predictive modelling. The individual steps can be performed in various software, such as Statistica, SPSS, SPSS Modeler, S+, Matlab, WEKA or R.

METHODS

Workflow of data mining

As already mentioned, data mining can be considered as an innovative connection of various methods of multivariate data analysis. Methodology of the complex DM approach always incorporates process workflow of analytical steps. Example of such approach is the CRISP DM methodology describing life cycle of DM project and their interconnections [4]; this methodology was also adopted in our article and educational materials.

According to CRISP-DM methodology the DM project life cycle consists of six phases; their order and direction of crossing between them is not strictly given and the movement in the scheme is based on the results of the previous phase (the arrows in the scheme shows the most common paths). The outer circle symbolizes cyclical nature of data analysis which is

Figure 1: DM workflow according to CRISP-DM methodology (taken from CRISP-DM)

repeated until the solution is found. The knowledge gained in one cycle can generate new questions and new cycles utilizing experiences from the previous cycles.

Understanding

This initial phase focuses on understanding the analysis objectives and requirements, and then converting this knowledge into a data mining problem definition and a preliminary plan designed to achieve the objectives. For example, in clinical data analysis this is the preliminary phase of literature review of given clinical problem (terminology, cut-offs, known correlations of variables etc.). Although it looks rather simple, this information is strategically important during the multivariate analysis. Limited knowledge on importance and meaning of variables can result into biased or uninterpretable results and during multivariate analysis these problems should not be necessarily revealed. Preliminary phase should be also the power and assessment of the necessary sample size.

Data Understanding

The data understanding phase starts with an initial data collection and proceeds with activities in order to get familiar with the data, to identify data quality problems, to discover first insights into the data, to detect interesting subsets to form hypotheses for hidden information. Wide set of univariate and multivariate analyses can be adopted for this exploratory analysis (Figure 2).
